# **Earth Integrated Heating and Cooling System**

Amit Bhuradia (2019chb1037)

Anchal Gupta (2019chb1038)

Arpita Singh (2019chb1042)

Manasi Dilip Sardesai (2019chb1048)

Mohamed Mazhar Laljee (2019chb1051)

A report submitted for the degree of Bachelor of Technology in Chemical Engineering

**Department of Chemical Engineering** 

April 2022

# Certificate

This is to certify that the B. Tech project titled "Earth Integrated Heating and Cooling System" prepared by

- 1. Amit Bhuradia 2019chb1037
- 2. Anchal Gupta 2019chb1038
- 3. Arpita Singh 2019chb1042
- 4. Manasi Dilip Sardesai 2019chb1048
- 5. Mohamed Mazhar Laljee 2019chb1051

is approved for submission for the course on Development Engineering Project in the Department of Chemical Engineering, Indian Institute of Technology, Ropar.

Signature of Examiner and Guide/s

Dr. Navin Gopinathan & Dr. Sarang Gumfekar

Assistant Professors

Department of Chemical Engineering

IIT Ropar

# Acknowledgement

We would like to express a deep sense of thanks and gratitude to our course instructors Dr. Navin Gopinathan and Dr. Sarang Gumfekar. This would not have been possible without them, as all through the course they have guided us and corrected us at every wrong turn. Their constructive criticism and constant motivation contributed to the success of this project. We would also like to thank Mr. Prabhjot Singh, 4th year Civil Engineering undergraduate, IIT Ropar for his help with the DesignBuilder simulation.

Last but not the least, we would like to thank all those who have helped directly or indirectly towards the completion of this project.

## **Abstract**

Excessive greenhouse gas emission is a serious concern worldwide and scientists are in search of more environment friendly alternatives of the existing technologies. The search is still on for more environment friendly and efficient heating and cooling systems. Ground coupled heat exchanger that exchanges energy with the ground for heating and cooling purposes is a new and emerging technology with immense potential. Extensive research on increasing the performance and reducing emissions from the same is being done. In this study we modeled two GCHE technologies namely earth air heat exchanger (EAHE) and ground source heat pump (GSHP) for a two storey building in New Delhi. The design calculations, assumptions have been clearly mentioned and other work including python code file and DWSIM model used for system modeling are provided in the annexure. The monthly COP of the GSHP system are in the range of 0.9-3.8 and those of EAHE system are in the range 3.696 - 12.019 making it more efficient than most conventional systems having an average COP of 3.5. The system can further be improved with the integration of solar panels for heating of circulating fluid or for providing the power supply to run the system.

Keywords: ground coupled heat exchanger, earth air heat exchanger, ground source heat pump

v: velocityCp: heat capacityqt: surface heat flux

 $h_{\perp}$ : combined heat transfer coefficient

 $T_s$ : radiant surface temperature

 $T_{ref}$ : room temperature

 $\eta 0$ : efficiency of the cell at 298 K.

ηel: electrical efficiency

 $\beta$ : silicon efficiency temperature coefficient

Tcell: temperature of one cell

S: heat absorber panel surface area

Qt: total heat collected in the storage tank

Qp: constant heat input from a circulation pump

Qu: useful energy gain delivered by the collector to the storage tank

Qs: stored energy as specific heat in the panel

 $\dot{m}$ : fluid's mass flow rate  $C_P$ : specific heat capacity

T: temperature at any section along the pipe

r: inner radius of the pipe

h: inside heat transfer coefficient

x: length coordinate,

T<sub>w</sub>: pipe wall temperature or earth temperature. Q: ventilation rate/volumetric flow rate of air

P: number of occupants
A: area of the ventilation zone
R<sub>p</sub>: air flow required per person
R<sub>a</sub>: air flow required per unit area

f: friction factor,

L: total length of the tube,
D: diameter of the tube,
va: velocity of the air
P: principal investment

CF: Cash flow interest rate

#### 1. Introduction

Widespread industrialisation and an increase in the standard of living of people has led to increased greenhouse gas emissions which cannot be sustained by the planet's ecosystem. The high heat trapping potential of these gasses has caused an increase in average atmospheric temperatures worldwide, and other undesirable effects on climatic patterns. To escape the impact of resulting oppressive weather conditions, it is necessary to use heating and cooling systems to maintain thermal comfort indoors. This helps occupants of a conditioned space remain at ease, and ensures higher levels of alertness, agility and productivity, and maintain better health, all of which are essential to carry out daily activities efficiently.

Out of the total energy consumption in buildings, a large chunk (35%) is spent on heating, ventilation and air conditioning (HVAC) requirements [1]. High energy use by conventional HVAC systems and the corresponding CO<sub>2</sub> emissions, and heat pumping to the atmosphere further add to the already alarming rise of global temperatures, resulting in a decrease in energy demand for heating but a much larger increase for cooling. A Swiss study predicts heating demand to fall by 36-58% and cooling demand to increase by a whopping 223-1050% by 2100 [2]. The increase in cooling demand as a percentage of total households can be seen in Fig. 1. This constitutes a vicious climate change positive feedback loop which must be broken at all costs. All this coupled with the frequent breakdown of equipment, associated maintenance and the risk of leakage of toxic working fluids to the environment makes the operation of conventional HVAC systems simply inefficient and unsustainable.

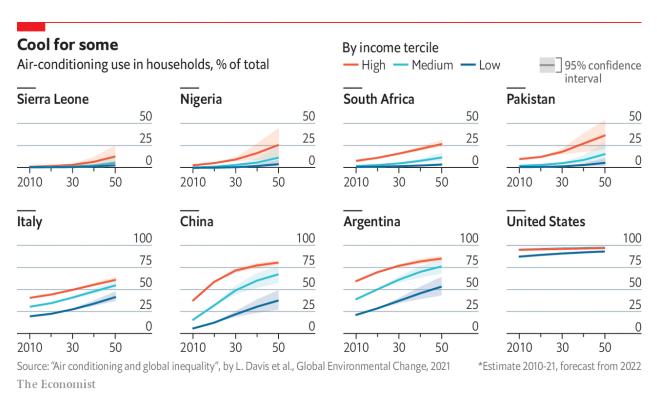

Fig. 1: Increase in Cooling Demand in Various Countries Adapted from [3]

Based on the above discussion, there is a dire need to adopt novel, energy efficient and environmentally benign technologies for heating and cooling of spaces. Some of these technologies exploit the phase change properties of substances, while some others work on the principle of energy storage in salt solutions. Another class of technologies based on geothermal energy is gaining widespread adoption and research interest. These systems can be coupled with renewable energy sources such as solar panels to reduce CO<sub>2</sub> emissions and grid dependence while meeting electricity demand for operating the system components.

Underground heat exchangers (geothermal based) that exchange energy with the ground for heating and cooling purposes are called Ground Coupled Heat Exchangers (GCHEs). The ground, whose temperature is relatively constant throughout the year, acts as a heat source in winters and as a heat sink in summers. Such systems have the advantage of being highly energy-efficient, environmentally friendly, easy to control, noise-free, cost-effective, providing good thermal comfort, having a stable capacity and requiring simple equipment. Disadvantages include high upfront costs and a lack of trained technicians and contractors [4]. However, the disadvantages are greatly outweighed by the advantages, because of which GCHEs have attracted widespread attention. Despite this, not a lot of research is available on the topic, especially those which compare two different technologies belonging to the class of GCHEs. Hence, in this study, we will be comparing the performance of two different GCHE technologies: Earth-Air Heat Exchangers (EAHEs) and Ground Source Heat Pumps (GSHPs) in a setting based out of New Delhi.

#### 2. Literature Survey

#### 2.1. Earth Air Heat Exchanger

The earth-air heat exchanger (EAHE) is a series of pipes buried underground at a particular depth through which fresh atmospheric air flows and gets cooled in summer and warmed in winter. The ambient air passing through the pipes exchanges heat with the pipe walls, which are in direct touch with the surrounding subsurface environment, transmitting heat via conduction and convection processes. The opposite end, which acts as an outlet, allows air to enter a structure. The thermal characteristics of the ground and the heat transfer between the pipes and the ground are connected to the performance of EAHE. closely Conduction, convection, and radiation are the heat transport processes in soil. Conduction occurs throughout the soil, although the solid and liquid elements carry the majority of the heat. With the exception of quick water penetration following significant rainfall, convection is typically modest.

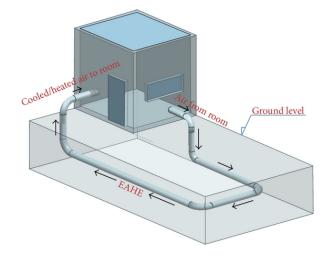

Fig. 2: Schematic of Earth-Air Heat Exchanger System. Adapted from [5].

Here for our design, we are building a system that works for a two-storey building. The main idea is to use the air present in the atmosphere to heat the environment inside the house in winters and cool

it during summers. The material of the pipe to be laid underground depends on various factors. The comparison table is displayed below:

Table 1: Comparison Table for Tube material Selection Analysis. Adapted from [6].

| S.no. | Material  | Conductivity in W/mk | Resistance to corrosion | Cost        |
|-------|-----------|----------------------|-------------------------|-------------|
| 1     | Copper    | 385                  | Medium                  | Very Costly |
| 2     | Aluminium | 205                  | High                    | Costly      |
| 3     | Brass     | 109                  | Medium                  | Costly      |
| 4     | Iron      | 79.5                 | Low                     | Costly      |
| 5     | Steel     | 50.2                 | High                    | Costly      |
| 6     | PVC       | 0.19                 | High                    | Cheaper     |

PVC pipes are generally used as they are readily available, inexpensive, and easy to install. But the main disadvantage is it gets brittle over time and can crack, break, or even shatter. The presence of air compressor lubricants in the line, as well as heat from compressed air, hastens the deterioration of PVC. Due to the airborne, razor-sharp shrapnel, these failures, when paired with pressured air, have the potential to be lethal. While aluminum is non-corrosive and remains leak-free, unlike other pipe systems. Considering the high cost of producing compressed air, reducing compressed air consumption by eliminating leaks over the life of the system, the aluminum pipe becomes a more recommendable material.

Since the air blown inside is directly sucked from the atmosphere, it can be contaminated, hence we will need air filters. Some of the air filters are listed below.

Table 2: Comparison Table of Air Filters. Adapted from [7].

| S.no. | Air filters   | Efficiency | Pros   | Cons   |
|-------|---------------|------------|--|--|
| 1     | НЕРА          | 99.97%     | Captures large pollutants, cost effective, and changes in a few years. | Ineffective against fumes, gasses and odors. Mold sores settle on the filter.      |
| 2     | UV light      | 99%        | Kills molds, germs, exceptional indoor quality.                        | Costly. Ineffective to dust or allergens, gases, fumes, cigarettes. O2 to O3       |
| 3     | Electrostatic | 98%        | Cost effective, reusable   | Struggle to filter large particles, poor choice for people with respiratory issues |

| 4 | Washable      | 75%    | Cost-effective, washable, Long lasting.                   | High maintenance, Complete drying after washing else source to pathogens.                                    |
|---|---------------|--------|---|--|
| 5 | Media filters | <20%   | Low maintenance, large surface area, traps pollutants     | Ineffective in filtering odours.   |
| 6 | Spun glass    | 20%    | Cheap, capture lint and dust.                             | Small surface area, ineffective against smaller pollutants, a poor choice for asthma patients, gets clogged. |
| 7 | Pleated       | 20-25% | Traps debris, large surface area, lasts longer, reusable. | Expensive, heat/cooling system will lose efficiency sooner   |

The MERV ratings play a vital role in choosing the best air filters. MERV stands for minimum efficiency reporting values.

Table 3: MERV Ratings for different types of filters. Adapted from [8].

| MERV Rating      | Air Filter will trap<br>Air Particles size<br>.3 to 1.0 microns | Air Filter will trap Air<br>Particles size<br>1.0 to 3.0 microns | Air Filter will trap Air Particles size 3 to 10 microns | Filter Type  Removes These Particles |
|------------------|---|--|---|--------------------------------------|

The MERV value is from 1 to 20. Higher MERV values correspond to a greater percentage of particles captured on each pass. The scale is designed to represent the performance of a filter when dealing with particles in the range of 0.3 to 10 micrometers. With a MERV 16 or above filter capturing more than 95% of particles over the full range is possible. We are using an air blower, a single pipe heat exchanger, air filters to enhance the air quality and pipes to be laid underground.

#### 2.2. Ground Source Heat Pump (GSHP)

A ground source heat pump is a heating/cooling system that employs a heat pump to transfer heat to or from the ground, taking advantage of the earth's relatively constant temperatures throughout the seasons. It consists of three units whose functionalities are explained below.

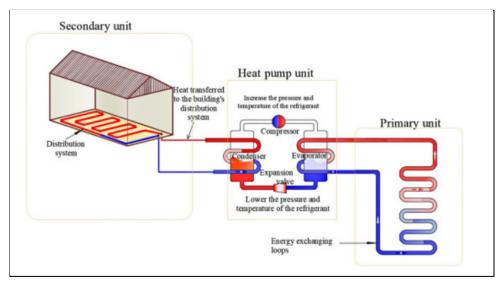

Fig. 3: Schematic of Ground Source Heat Pump (GSHP) System Source: Adapted from [9].

- 1. <u>Heat Exchanger Unit:</u> Facilitates transfer of heat to or from the ground to the circulating fluid which is ultimately brought in thermal contact with the circulating fluid in the heat pump.
- 2. <u>Heat Pump Unit:</u> Extraction of heat from the circulating fluid in the heat exchanger and transferring it to the liquid in the secondary loop or the building loop
- 3. <u>Secondary Loop/Building Loop:</u> Comprises of a piping network for transfer of heat in and out of the building

#### 2.2.1 Heat Exchanger

There are two types of GSHP systems: Vertical GSHP and Horizontal GSHP. Vertical GSHP consists of a vertical U-tube heat exchanger and is installed using deep drilled boreholes. It requires less outdoor space and is more energy efficient compared to horizontal GSHP systems. Considering the following advantages of the vertical GSHP system, we have selected it for our model. It consists of a <u>vertical U-tube Heat Exchanger</u>.

A U-tube Heat Exchanger consists of a circulating fluid, U- tube, grout and the surrounding ground. A U-bend configuration is used where the two vertical U-tube pipes are connected with 180 degree fitting. As the fluid descends, the temperature difference in the fluid and the earth mass causes heat flow. In our model, we have taken <u>water as the coolant</u>.

For designing the heat exchanger, we require certain physical properties such as thermal conductivity, viscosity and specific heat capacity. All these values have been taken from Process Heat Transfer by DQ Kern.

Table 4: Physical properties of water. Adapted from [10]

| Density (p)                | 998.23 kg/m <sup>3</sup>                   |
|----------------------------|--|
| Thermal Conductivity (k)   | 6.15 * 10 <sup>-7</sup> kW/m °C            |
| Viscosity (v)              | 0.86 * 10 <sup>-3</sup> Kg/m.s             |
| Specific Heat Capacity (C) | 4.179 k J kg <sup>-1</sup> K <sup>-1</sup> |

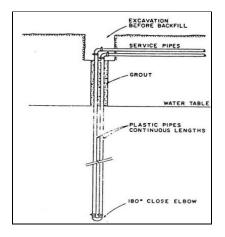

Fig 4: U-tube heat exchanger. Adapted from [9]

**Table 5: U - tube dimension. Adapted from [10]** 

| Tube OD | 19.065 mm |
|---------|-----------|
| Tube ID | 15.392 mm |
| BWG     | 15        |
| Length  | 6 m       |

#### 2.2.2 Heat pump

A heat pump is a mechanical device that is used to transfer thermal energy between spaces using electricity much like a refrigerator. When employed in a GSHP system, in the winter season it is used to supply energy in the house for heating purposes and in the summer season it is used to remove heat from the house for cooling. It consists of four subcomponents namely evaporator, compressor, condenser and expansion valve along with a circulating fluid or refrigerant.

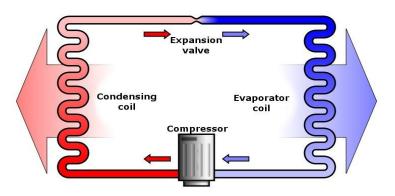

Fig 5: Heat Pump Schematic. Adapted from [11]

The heat pump cycle for space heating begins with extraction of heat from the heat carrier fluid which in our case is the working fluid of the heat exchanger by the refrigerant in the evaporator. This causes the refrigerant in the evaporator to boil, becoming a low pressure vapor which is then fed into the compressor. After compression, the refrigerant now at a higher temperature and pressure, passes into the condenser. At the condenser, the high pressure vapor transfers its energy to the secondary

loop or the building loop and condenses into liquid form. From there it goes into the expansion valve which further reduces its temperature and pressure and the cycle repeats again. For space cooling, the working principle of the system is reversed. [17]

The performance indicator for a heat pump is its coefficient of performance or COP which is defined as the ratio of input power to the heat pump and output power.

$$COP = \frac{power input to the heat pump}{power output}$$
 (1)

Taking environmental concerns into account, the choice of refrigerant for the heat pump is also very important. An ideal refrigerant should be one that does not contribute towards ozone layer depletion and has a minimum global warming potential. Table below visualizes the difference in properties of the earlier used R22 (CHClF<sub>2</sub>) and R290 (propane) as a refrigerant.

R22 R290 **ODP** 0 0.055 **GWP** 1300 3 Molecular mass (kg/kmol) 86.5 44.103 Normal boiling point (°C) -40.8-42.1Critical temperature (°C) 96.0 96.7

Table 6: Characteristics of R22 & R29. Adapted from [12]

#### 2.2.3 Radiant Heating/Cooling System

A popular category of heating, ventilation and air conditioning system (HVAC) are radiant heating and cooling systems in which heat is exchanged by both convection and radiation. The total amount of heat removed by a radiant surface can either be calculated separately as cited in Chapter 6 of ASHRAE Handbook, HVAC Systems and Equipment (ASHRAE 2012a) or separately using a combined heat transfer coefficient as recommended by ISO 11855 [36]. For the design of radiant systems the latter is generally used and the formulae for the same is given below.

$$q_t = h_{tot} | T_s - T_{ref} | \tag{2}$$

Where,  $q_t$  is surface heat flux

 $\boldsymbol{h}_{tot}$  : combined heat transfer coefficient

 $T_{\rm s}$ : radiant surface temperature

 $T_{ref}$ : room temperature

#### 2.3 Solar Panel

#### 2.3.1 Introduction

A solar panel which is also known as a photovoltaic module is a device which generates the direct current (D.C) electricity that uses the sunlight as an energy source. The assembly of solar cells which are mounted in a specific frame for installation is called solar panels or PV panels and the assembly of these panels is called arrays.

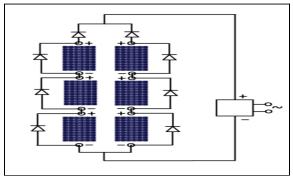

Fig 6: Solar cell to PV system Adapted from [13]

Fig 7: Connection of Panels with diode Adapted from [13]

#### **2.3.2** Integration of solar panels:

Integrated solar is when solar electricity is built in as part of the original structure rather than as a separate module. Solar energy can be collected in two ways: thermally or through photovoltaic cells. Integrated solar panels are weatherproof and as tough as regular roof tiles, but they also feature photovoltaic cells for electricity generation. During the heating season, mounted solar panels will collect energy and store it in seasonal heat storage.

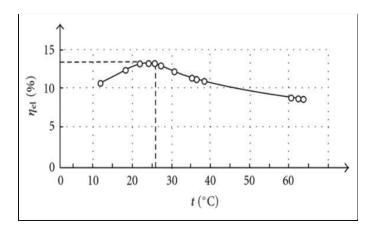

#### 2.3.3 Performance and efficiency analysis of solar panels:

Solar cells convert solar energy into electricity with a very low efficiency of less than 20%, with more than 80% of the energy being dumped into the environment. There are two types of solar panels which are crystalline and non-crystalline panels made of silicon. Poly-crystalline panels are cheaper and easier to manufacture whereas mono-crystalline panels are most efficient but production cost is high. Around 80% of total solar panels are based on crystalline technology which are mono-crystalline and poly-crystalline silicon solar panels and non crystalline technology based on thin-film solar panels.

Efficiency of the solar cells are defined as the electrical and thermal efficiency the formula for the same is,

$$\eta_{el} = \eta_0 [1 + \beta (T_{cell} - 298 \text{ K})$$
 (3)

Where,  $\eta 0$  is the efficiency of the cell at 298 K,  $\eta el$  is electrical efficiency,  $\beta$  is silicon efficiency temperature coefficient and Tcell is temperature of one cell.

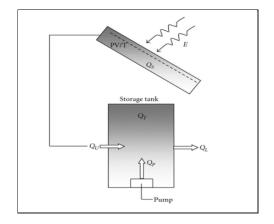

Fig 8: Efficiency w.r.t Temperature plot Adapted from [14]

Fig 9: Energy flow in the system Adapted from [15]

Thermal efficiency is defined as follows,

$$\eta_T = (Q_U + Q_S)/E .S = (Q_T + Q_L - Q_P + Q_S)/E .S$$
(4)

Where, S: heat absorber panel surface area

Qt: total heat collected in the storage tank

Op: constant heat input from a circulation pump

Qu: useful energy gain delivered by the collector to the storage tank

Qs: stored energy as specific heat in the panel

Efficiency of solar panels also depends on the angles so when we integrate the solar panels then it should be considered that solar panels should be put in the right direction with an optimum angle so we can get the maximum sunlight on the arrays and then can get maximum efficiency.

So here basically we use some terms of angles like Tilt angle which decides the optimum angle to get max sunlight on the solar panels. Azimuth angle defines the direction of the sun for the solar panels and it varies throughout the day and other angles are angle of altitude, angle of latitude

Energy produced by a solar panel is calculated by,

$$E = A \times r \times H \times PR \tag{5}$$

Where, A = solar panel area(m²) r = solar panel efficiency H = Annual average solar radiation PR = performance ratio (default value = 0.75)

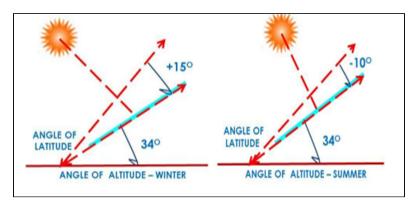

Fig 10: Angle of Altitude and Latitude in Different Seasons. Adapted from [16]

#### 2.4. Data collection

#### 2.4.1 Ground Temperature Data for New Delhi

The monthly distribution of the earth's temperature in New Delhi at a depth of 1.5 m can be seen in Fig. 11. This gives the limiting temperature that the working fluid can reach when exchanging heat with the ground.

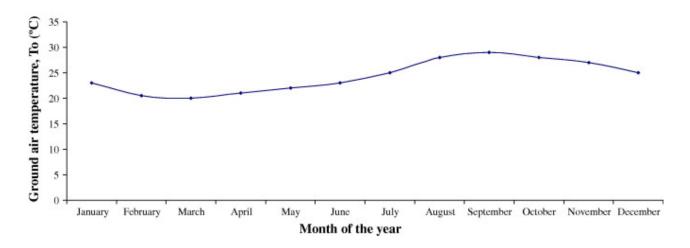

Fig 11: Monthly Average Ground Temperature for New Delhi at a Depth of 1.5 m. Adapted from [18]

#### 2.4.2 Climatic Data for New Delhi

The climatic data for New Delhi is shown in Table 7. It helps understand the annual weather patterns in New Delhi, and will primarily be used in calculations pertaining to the operation of the earth air heat exchanger (EAHE).

Table 7: New Delhi Climatic Data. Adapted from [19]

| Month     | High / Low (°C) |
|-----------|-----------------|
| January   | 20° / 8°        |
| February  | 24° / 11°       |
| March     | 30° / 16°       |
| April     | 37° / 23°       |
| May       | 40° / 27°       |
| June      | 39° / 28°       |
| July      | 35° / 28°       |
| August    | 34° / 27°       |
| September | 34° / 25°       |
| October   | 33° / 21°       |
| November  | 28° / 14°       |
| December  | 22° / 9°        |

#### 3. Problem Statement

Earth experiences climate change from extreme winters to extreme summers. Pertaining to the irregular climate change in past few decades humans found it difficult to sustain. Excessive usage of air conditioners is the leading cause of atmospheric degradation. In this report we propose an environment friendly method for heating and cooling of houses in winters and summers respectively. In our problem we propose to build a model based on GCHE or Ground Coupled Heat Exchanger technology. This technology has two types of systems EAHE (Earth Air Heat Exchanger) and GSHP (Ground source heat pump). Our main aim is to build an efficient system that can be used during extreme climatic conditions in India while keeping cost in mind. Specifically, we are proposing this model for a two storey residential building in New Delhi occupied by 4 people. The area of each storey is 300 sq ft, giving the total area of the building as 600 sq ft.

#### 4. Methodology, Results and Discussion

#### 4.1 Determining Heating and Cooling Loads

Since the project is based on providing thermal comfort inside a house, the first step after defining the problem statement and project scope is to determine the heating and cooling loads for the house in question. A simulation software called 'DesignBuilder', widely used by engineers for building design and energy simulations, was employed for the purpose. A mockup of a two storey building (area of each storey = 300 sq ft) having a window wall ratio (WWR) of 30% and housing 4 occupants was created, with the geographical area set to New Delhi. The total space volume is 6889.77 cubic ft. The U value for the roof is 0.25 W m<sup>-2</sup> K<sup>-1</sup>, and that for the walls is 0.352 W m<sup>-2</sup> K<sup>-1</sup>. Solar panels of area 300 sq ft were added to the roof to see if they could fulfill the heating and cooling requirements. The simulation was then run to obtain the results.

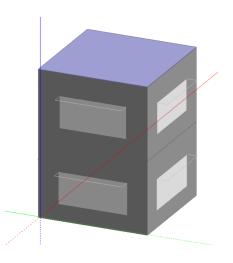

Fig 12 : Target Building Mockup

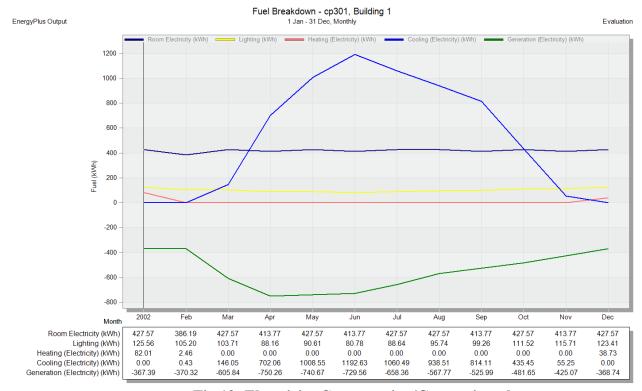

Fig 13: Electricity Consumption/Generation plot

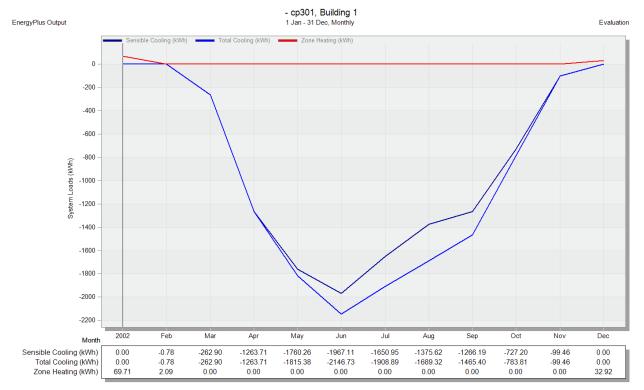

Fig 14: Heating and Cooling Loads

#### **4.2 Heat Transfer Governing Equation**

The next step was to derive a governing equation for the heat transfer operation. To do this, an energy balance is carried out on a section of the horizontal heat exchanger pipe.

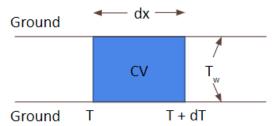

Fig 15: Pipe Section

In deriving the equation, we assume:

- 1. Steady state
- 2. Uniform flow
- 3. Constant earth temperature
- 4. Temperature of pipe walls equals earth temperature
- 5. Heat transfer resistance is only due to convection

The energy balance on the control volume (CV) gives:

$$\dot{m}C_{p}\frac{T+dT-T}{dx} = 2\pi rh \, dx(T_{w} - T) \tag{6}$$

where m is the fluid's mass flow rate,  $C_P$  is its specific heat capacity, T is its temperature at any section along the pipe, r is the inner radius of the pipe, h is the inside heat transfer coefficient, x is the length coordinate, and  $T_w$  is the pipe wall temperature = earth temperature. Upon integrating (6), using the initial condition that  $T = T_{in}$  (inlet temperature) at x = 0, and rearranging, we get the relation for outlet temperature ( $T_{out}$ ) as (please refer to the Annexure for the complete derivation):

$$T_{out} = T_w + (T_{in} - T_w)e^{-\frac{2\pi r h x}{\dot{m}C_p}}$$
 (7)

This equation can also be used for vertical heat exchanger pipes if variation of the earth's temperature with depth is neglected. The value of Earth's temperature in New Delhi for each month can be read from Fig. 11 to be used as  $T_w$  in (7).

#### 4.3. Earth Air Heat Exchanger (EAHE)

#### 4.3.1. Heat Transfer Equation Accuracy

Before using the derived equation (7) for calculations specific to our case, it is essential to gauge its accuracy if possible. For this, we compare the equation's output with results of an experiment carried out at Ajmer. Here, an EAHE having an inner diameter of 0.15 m and length of 23.42 m is used for heating and cooling of air (density =  $1.225 \text{ kg/m}^3$ , specific heat capacity =  $1006 \text{ J kg}^{-1}$  K<sup>-1</sup>). The air velocity v (and hence mass flow rate) is varied from 2 to 5 m/s. The months of January (inlet air temperature =  $20.6 \, ^{\circ}\text{C}$  and ground temperature =  $26 \, ^{\circ}\text{C}$ ) and March (inlet air temperature =  $43.7 \, ^{\circ}\text{C}$  and ground temperature =  $30 \, ^{\circ}\text{C}$ ) are considered [20, 21]. The only missing parameter is the inside heat transfer coefficient h which can be calculated using the correlation h = 2.8 + 3v (8), given by A. Chel et al [18]. The results are compared in Tables 8 and 9.

Table 8: Experimental vs Calculated Results for Heating in January Data Source: [20]

|                                 | 2 m/s  | 3.2 m/s | 4 m/s  | 5 m/s  |
|---------------------------------|--------|---------|--------|--------|
| Exit temperature (Experimental) | 25.4   | 25.1    | 24.9   | 24.7   |
| Exit temperature (Calculated)   | 25.42  | 25.24   | 25.17  | 25.11  |
| % difference                    | 0.076% | 0.567%  | 1.092% | 1.664% |

Table 9: Experimental vs Calculated Results for Cooling in January Data Source: [21]

|                                 | 2 m/s  | 3.2 m/s | 4 m/s  | 5 m/s  |
|---------------------------------|--------|---------|--------|--------|
| Exit temperature (Experimental) | 31     | 32      | 32.5   | 33.7   |
| Exit temperature (Calculated)   | 31.47  | 31.92   | 32.10  | 32.26  |
| % difference                    | 1.527% | 0.242%  | 1.228% | 4.287% |

The percentage error between calculated and experimental results is less than 5% indicating a high degree of accuracy, which means that the equation together with the heat transfer coefficient correlation is good for deployment in real world scenarios.

#### 4.3.2. Building Ventilation Requirements

Before we use the heat transfer equation for our case, its parameters must be determined.

The mass flow rate of air, its velocity and heat transfer coefficient will depend on the ventilation requirements of the building. This is given by:

$$Q = R_p P + R_a A \tag{9}$$

where Q is the the ventilation rate/volumetric flow rate of air, P is the number of occupants (4 here), A is the area of the ventilation zone (600 sq ft here),  $R_p$  is the air flow required per person (5 cfm/person for residential area) and  $R_a$  is the air flow required per unit area (0.06 cfm/sq ft for residential area). The values of  $R_p$  and  $R_a$  are obtained from the ASHRAE 62.1 standards [22]. Using (9), the volumetric flow rate of air is obtained as 56 cfm or 0.02643 m³/s. A metric called Air Changes per Hour (ACH) is used to gauge the ventilation of a given space. It is given by:

$$ACH = \frac{60 \times Q}{Space\ Volume} \tag{10}$$

Equation (10) gives an ACH of 0.49, which is greater than the 0.35 recommended by ASHRAE for residential areas. Thus, we can safely restrict the operation of our EAHE to this flow rate. The operation can be sustained by the MB840-D blower made by Oriental Motor, having an impeller diameter of 3.15 in and priced at USD 76. Fig. 16 shows the blower, and Table 10 its specifications [23]. It will be operated at a 50 Hz single phase voltage of 200 V, corresponding to an input power of 28 W.

Fig. 16: MB840-D Blower. Adapted from [23]

**Table 10: Blower Specifications** 

Source: [23]

| Model   | Voltage          | Frequency | Current | Input | Speed | Max. Air Flow |      | Max. Static Pressure |                    | Noise Level | Capacitor |
|---------|------------------|-----------|---------|-------|-------|---------------|------|----------------------|--------------------|-------------|-----------|
| Wiodei  | VAC              | Hz        | Α       | W     | r/min | m³/min        | CFM  | Pa                   | inH <sub>2</sub> O | dB (A)      | μF        |
|         | Single-Phase 200 | 50        | 0.14    | 28    | 2800  | 1.6           | 56.5 | 152                  | 0.61               | 55          |           |
|         | Single-Phase 200 | 60        | 0.18    | 32    | 3200  | 1.8           | 63.5 | 221                  | 0.886              | 58          |           |
| MB840-D | Single-Phase 220 | 60        | 0.18    | 35    | 3350  | 1.8           | 63.5 | 226                  | 0.906              | 59          | 2.5       |
| 1       | Single-Phase 230 | 50        | 0.15    | 35    | 2850  | 1.6           | 56.5 | 157                  | 0.63               | 55          |           |
|         | Single-Phase 230 | 60        | 0.18    | 36    | 3350  | 1.8           | 63.5 | 226                  | 0.906              | 59          |           |

#### 4.3.3. Other Calculation Parameters

For this problem, we have chosen a heat exchanger pipe having inner diameter 0.15 m and length 30.48 m. Based on this, the heat transfer area comes out to be 14.363 m², the air velocity is 1.4956 m/s, and the inside heat transfer coefficient is 7.2868 W m⁻² K⁻¹. The mass flow rate can be calculated by multiplying the volumetric flow rate with the density. The density of the air, however, will vary with temperature, and so will the viscosity. These properties will be used in heat exchanger calculations corresponding to every month of the year, and looking up the values every time or reading them from graphs can be tedious. To circumvent this issue, simple correlations have been developed with the help of scipy.optimize library in Python. The training datasets for both properties include values at -10, 0, 10, 20, 30, 40, 50 and 60 °C and 1 bar, while testing datasets include values at 5, 15, 25 and 35 °C and 1 bar (data source: The Engineering Toolbox [24, 25]).

A 2nd order curve of the form  $aT^2 + bT + c$  is fit to the density training data. The  $R^2$  and Root Mean Square Error (RMSE) for the training data are 0.999975 and 0.000464 respectively, and those for the testing data are 0.999707 and 0.000779 respectively. The equation parameters are shown in Table 11, and the curve fit in Fig. 17.

**Table 11: Constants of 2nd Order Density Curve** 

| <b>a</b> 1.38690477e-05 |                 |  |  |  |  |
|-------------------------|-----------------|--|--|--|--|
| b                       | -4.69226191e-03 |  |  |  |  |
| С                       | 1.29223214e+00  |  |  |  |  |

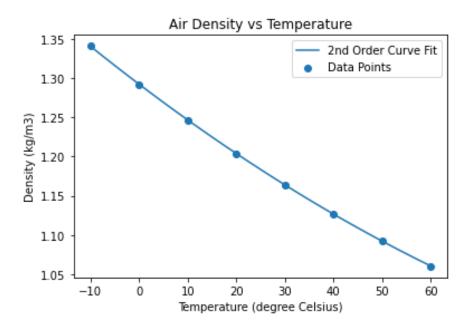

Fig. 17: Air Density vs Temperature with Curve Fit

Similarly, a line of the form aT + b is fit to the viscosity training data. The  $R^2$  and RMSE for the training data are 0.999756 and 1.708e-8 respectively, and those for the testing data are 0.998698 and 1.936e-8 respectively. The equation parameters are shown in Table 12, and the curve fit in Fig. 18.

**Table 12: Constants of Linear Viscosity Fit** 

| а | 4.76666667e-08 |
|---|----------------|
| b | 1.71533333e-05 |

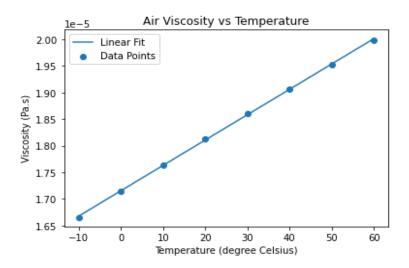

Fig. 18: Air Viscosity vs Temperature with Line Fit

Since the correlations perform very well, they can be used for calculation purposes without any worries (please refer to the Annexure for the complete correlation derivation codes). The last parameter to be considered is the inlet air temperature, which not only appears in the heat transfer equation but also decides the density and viscosity values to be used. This is given by the climatic data for New Delhi.

Now that we have collated all the data, we can proceed to calculations.

#### 4.3.4. Heat Exchanger Calculations

For calculation of various aspects of EAHE operation, a simple Python code was developed, a snippet of which is shown in Fig. 19. Important libraries are imported, arrays for maximum and minimum inlet temperatures and ground temperatures are created, other properties and parameters are defined, mass flow rates are calculated with the help of the density correlation, and the heat transfer equation is implemented to calculate  $T_{out}$ . Based on the results for  $T_{out}$ , heat duty, effectiveness, COP, etc. can be calculated (snippet shown in Fig. 19, please refer to the Annexure for the complete code).

```
import pandas as pd
import numpy as np
import math
import matplotlib.pyplot as plt
import matplotlib.ticker as mticker
Tw=np.array([23,20.5,20,21,22,23,25,27.5,28.5,27.5,26.5,25]) # deg C
Tin_min=np.array([8,11,16,23,27,28,28,27,25,21,14,9]) # deg C
Tin_max=np.array([20,24,30,37,40,39,35,34,34,33,28,22]) # deg C
air flow=0.02643 # m^3/s
Cp=1005 # J ka^-1 K^-1
blower power=28 # W
pipe ID=0.15 # m
pipe length=30.48 # m
area=14.363 # m^2
v=air_flow/(math.pi*pipe_ID**2/4) # m/s
h=2.8+3*v # W m^-2 K^-1
m_dot min=air_flow*(1.38690477e-05*Tin min**2-4.69226191e-03*Tin min+1.29223214e+00)
m dot max=air flow*(1.38690477e-05*Tin max**2-4.69226191e-03*Tin max+1.29223214e+00)
Tout_min=Tw+(Tin_min-Tw)*np.exp(-math.pi*pipe_ID*h*pipe_length/(m_dot_min*Cp))
print('Minimum outlet temperatures:')
print(Tout min)
print('\n')
Tout_max=Tw+(Tin_max-Tw)*np.exp(-math.pi*pipe_ID*h*pipe_length/(m_dot_max*Cp))
print('Maximum outlet temperatures:')
print(Tout_max)
```

Fig. 19: Python Code Snippet

The outlet air temperature (in °C) and exchanger heat duty (in W) results are shown in Table 13. The annual range of outlet air temperature is 19.841-28.678 °C, which is much narrower than the ambient temperature range of 8-40 °C. Further, as can be seen in Fig. 20, the outlet air temperature at any given instant for a particular month will lie within a very narrow band, enabling tight temperature control for all months. The width of this band varies in the range 0.216-0.575 °C. Thus, the EAHE

does an impressive job in maintaining thermal comfort in the house throughout the year and offsetting the impact of oppressive weather.

**Table 13: Outlet Temperatures and Heat Duties** 

| Month | Ground<br>Temp | Min<br>Temp | Max<br>Temp | Outlet<br>Temp for<br>Min Inlet | Outlet<br>Temp for<br>Max Inlet | Heat Duty<br>for Min Inlet<br>Temp | Heat Duty<br>for Max<br>Inlet Temp |

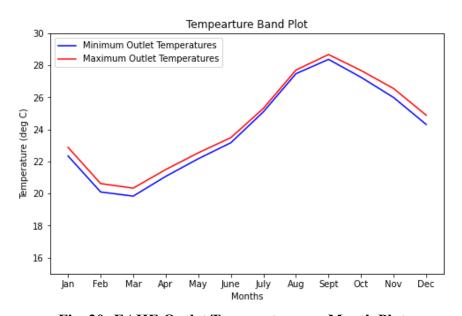

Fig. 20: EAHE Outlet Temperatures vs Month Plot

Pressure drop for the system is given by:

$$P = f \frac{L}{D} \rho \frac{va^2}{2}$$
 (11)

Where, f is the friction factor, L is the total length of the tube, D is the diameter of the tube,  $\rho$  is the density of the air and va is the velocity of the air.

Friction factor is the measure of the resistance to the fluid flow. It depends on the Reynolds number and varies for laminar and turbulent flow.

$$f = \frac{64}{Re}$$
 (for Laminar flow Re < 2300) (12)

$$f = \frac{64}{Re}$$
 (for Laminar flow Re < 2300) (12)  
 $f = (1.82log(Re) - 1.64)^{-2}$  (for turbulent flow Re > 2300) (13)

Where Reynolds number is given by the following expression:

$$Re = \frac{\rho vaD}{\mu}$$

(14)

Based on the correlations, the following values of air density and viscosity are obtained, which can then be used to calculate the pressure drop. The results are shown in Tables 14 and 15.

Table 14: Viscosity and density data with respect to temperature.

| N 41  | C 1T        | Т       | M (D            | D '(1 / 2)     |

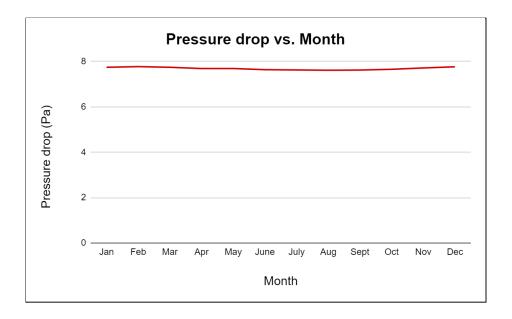

Fig. 21: Pressure drop v/s Month plot

Not only is the EAHE effective in maintaining thermal comfort, but also in efficiently using the available area for heat exchange with the ground, and performing better than conventional heating-cooling systems in terms of energy efficiency. This is indicated by high values of effectiveness, given by:

Effectiveness = 
$$(T_{out} - T_{in})/(T_w - T_{in})$$
 (15)

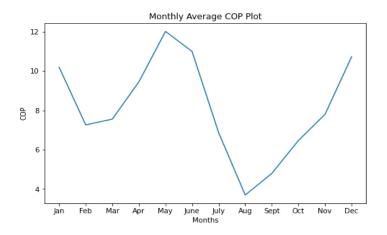

and Coefficient of Performance (COP), given by:

in Table 16. The annual range of effectiveness is 0.957-0.97, with a very high average of 0.964, indicating that the outlet air temperature nearly equals the ground temperature which is the limiting value. The monthly average COP is in the range 3.696-12.019, with an annual average of 8.153. This means that our EAHE is much more energy efficient than most conventional systems having an average COP of 3.5.

**Table 16: COP and Effectiveness** 

| Month | COP for   | COP for   | Average | Effectiveness | Effectiveness |
|-------|-----------|-----------|---------|---------------|---------------|
|       | Min Inlet | Max Inlet | Monthly | for Min Inlet | for Max Inlet |
|       | Temp      | Temp      | COP     | Temp          | Temp          |
| Jan   | 17.092    | 3.296     | 10.194  | 0.957         | 0.962         |

| Apr   | 2.178     | 16.726    | 9.452   | 0.963         | 0.969         |
| May   | 5.381     | 18.657    | 12.019  | 0.965         | 0.970         |
| June  | 5.365     | 16.631    | 10.998  | 0.965         | 0.969         |
| July  | 3.219     | 10.514    | 6.867   | 0.965         | 0.968         |
| Aug   | 0.538     | 6.854     | 3.696   | 0.965         | 0.968         |
| Sept  | 3.789     | 5.799     | 4.794   | 0.964         | 0.968         |
| Oct   | 7.121     | 5.816     | 6.469   | 0.963         | 0.967         |
| Nov   | 13.986    | 1.610     | 7.798   | 0.959         | 0.965         |
| Dec   | 18.176    | 3.277     | 10.726  | 0.957         | 0.963         |

From Fig. 22, it can also be seen that the COP is highest for the peak summer and winter months which is desirable as maximum heat exchange with the ground must take place to ensure thermal comfort. In some months, the average COP is much less than in the peak months due to the difference between inlet air and ground temperatures being relatively smaller, thus reducing the scope for heat exchange. However, it is still higher than the average of 3.5 for conventional systems.

#### Fig. 22: Average COP for each Month plot

Thus, it can be concluded that the EAHE is effective in maintaining a comfortable environment inside the house and is an environmentally friendly option when compared to other systems due to its high energy efficiency.

From the above analysis for our EAHE system COP was in the range of 0.538-18.657. Analysis by comparing our model with the existing one gave not so surprising results. In an EAHE system used in China where the temperature ranges from -0.5 to 14.3 °C it was found that the COP and Q decrease along with the growth of inlet air temperature but increase along with the pipe length. The COP and Q of EAHE could reach up to the maximum of 15.8 and 2.5 KW respectively when the inlet air temperature is -0.5°C. Whereas the COP decreases to 2.7 and Q to 0.4 KW respectively, when the inlet air temperature is 14.3°C. Within our model's temperature range at a maximum temperature of about 40°C in May the COP was 18.657. This is much higher than the COP from the existing model in China. Whereas for a minimum temperature of about 8°C in January the COP was 17.096. Even though at this temperature which is quite near to 14.3°C the COP is way higher in comparison. Thus we can say we successfully modeled an EAHE system to fulfill our goals.

#### 4.3.5 Cost Analysis

As previously discussed we use HEPA air filters for our EAHE system. The price of the HEPA filter is Rs 6000/- per piece.

Following are the specifications of the air blower we plan to use, based on the discussion in section 4.3.2.

1. Model: MB840-D by <u>Oriental motor</u>

2. Power: 28W

3. Impeller diameter: 3.15 in

4. Cost: Rs 5769.73/-

The model we are proposing is chosen to be at New Delhi in location. Since the system is working with suction pumps and Heat exchanger the electricity costs need to be estimated. The electricity tariffs for New Delhi are:

Table 17: Electricity tariffs for domestic usage in Delhi. Adapted from

| Sr.<br>No. | CATEGORY                                | FIXED CHARGES    | D CHARGES ENERGY CHARGES |                 |                 |                 |                 |  |  |
|------------|---|------------------|--------------------------|-----------------|-----------------|-----------------|-----------------|--|--|

| В          | > 2kW and ≤ 5 kW                        | 50 Rs./kW/month  | 2.00                     | 4.50            | 6.50            | 7.00            | 0.00            |  |  |
| С          | > 5kW and ≤ 15 kW                       | 100 Rs./kW/month | 3.00<br>Rs./kWh          | 4.50<br>Rs./kWh | 6.50<br>Rs./kWh | 7.00<br>Rs./kWh | 8.00<br>Rs./kWh |  |  |
| D          | >15kW and ≤ 25 kW                       | 200 Rs./kW/month | NS./KVVII                | NS./KVVII       | NS./KVVII       |                 |                 |  |  |
| E          | > 25kW                                  | 250 Rs./kW/month |                          |                 |                 |                 |                 |  |  |
| 1.2        | Single Point Delivery<br>Supply for GHS | 150 Rs./kW/month | 4.50 Rs./kWh             |                 |                 |                 |                 |  |  |

#### **Electricity:** (28 W air blower)

Now, the annual electricity consumption for the air blower is 81.76 kWh/year and the cost of grid electricity in India is Rs 3/kWh from table 17. Also, fixed charges per year is Rs 240/kW (Rs 20/kW/month). Therefore the annual electricity cost is given by,

Annual electricity cost = Rs 
$$(245.28/year + 23476.8/year)$$
 = Rs  $23722.08/year$ 

Now, total annual maintenance cost is equal to 10% of total cost which comes out to be Rs 2372.208/year. Hence the total annual cost is calculated as shown.

Total Annual cost = 
$$23770.26 + 2377.026 = \text{Rs } 26094.288/\text{year}$$

Now simple payback period is given by,

Simple payback period = 
$$\frac{Initial Investment(P)}{Annual net cash flow(CF)}$$
 (17)

Where, P is the initial investment

CF = annual uniform cash inflow(R) - Annual uniform cast outflow(M)

Now,  $P = \cos t$  of air filters +  $\cos t$  of air blower + Total pipe  $\cos t$  + Cost of installation. Therefore, P = 6000 + 5769.73 + 15802.63 + 4823.58 = Rs 32395.94

Discounted payback period = 
$$\frac{ln[\frac{Cf}{Cf - P^*r}]}{ln[1+r]}$$
Where  $r = i \times (1 - tax \text{ benefits})$  (18)

The suitable annual interest rates considered for EAHE are:

- 1. 4% interest rate normally offered by government sectors in India.
- 2. 7–8% is the interest rate normally offered by government banks.
- 3. 10–12% is the interest rate offered by private banking sectors.
- 4. 12–16% is the interest rate for any other private source

Using equations (17) and (18) the payback period can be calculated with a knowledge of P, CF and r.

#### 4.4 Ground Source Heat Pump (GSHP)

For providing thermal comfort inside the two storey building in question, we apply a different approach i.e. a ground source heat pump or GSHP system which primarily consists of three units as explained in section 2. We will now look at the design calculations of each unit one by one.

#### 4.4.1 Heat Exchanger Analysis

For the GSHP system, since we are using vertical ground heat exchangers, we have designed a Borehole field with the following specifications:

**Table 18:** Borehole field specifications

| Number of Boreholes          | 20        |
|------------------------------|-----------|
| Depth of Borehole            | 3 m       |
| Drilling diameter            | 120 mm    |
| Shank space                  | 95.325 mm |
| Distance between U-tube legs | 96 mm     |

For our model, we have taken the Outer diameter 19.065 mm and Inner diameter 15.392 mm of the U-tube heat exchanger. Based on this, we calculated the heat transfer area as follows:

Outer CSA = 
$$\pi * d_o *L = \pi * (19.065 * 10^{-3}) * 1 = 0.06 (m^2)$$
  
Inner CSA =  $\pi * d_i *L = 0.048 (m^2)$ 

The mass flow rate of water in the pipe is taken as 0.25 kg/s. The velocity of water comes out to be:

$$u = mass flow rate / (p * Inner CSA) = 1.346 m/s$$

The convective heat transfer coefficient of water is calculated using this expression [10]:

$$h_{i} = \frac{4200(1.35 + 0.02t)u^{-0.8}}{di^{0.2}}$$
 (19)

Where,  $u_t$  is the velocity of water in tube,  $d_i$  is the inner diameter of tube and t is the tube thickness.

For the sake of simplicity, we've used the ground surface temperature (Table-7) for different months as the vertical heat exchanger's inlet temperature. We have assumed that temperature does not vary with depth at any point below the ground level. Therefore, we directly used the equation (7) derived in section (4.2) to calculate the outlet temperature of the heat exchanger. Using inlet and outlet temperature, we calculated the heat exchanger duty (Q), which is given by:

$$Q = m * C * \Delta T \qquad (20)$$

**Table 19:** Heat Exchanger Outlet temperature and Heat duties

| Month    | L(m) | Mass flow (kg/sec) | v (m/sec) | Tin (deg C) | Tout (deg C) | Q (KW) |
|----------|------|--------------------|-----------|-------------|--------------|--------|
| Jan      | 6    | 0.25               | 1.346     | 15          | 22.97        | 8.327  |
| February | 6    | 0.25               | 1.346     | 17          | 20.99        | 4.169  |

| March     | 6 | 0.25 | 1.346 | 26 | 20.02 | -6.248  |
|-----------|---|------|-------|----|-------|---------|
| April     | 6 | 0.25 | 1.346 | 30 | 21.03 | -9.371  |
| May       | 6 | 0.25 | 1.346 | 35 | 22.05 | -13.53  |
| June      | 6 | 0.25 | 1.346 | 38 | 23.05 | -15.619 |
| July      | 6 | 0.25 | 1.346 | 35 | 25.03 | -10.416 |
| August    | 6 | 0.25 | 1.346 | 32 | 26.02 | -6.248  |
| September | 6 | 0.25 | 1.346 | 28 | 27    | -1.045  |
| October   | 6 | 0.25 | 1.346 | 25 | 26.99 | 2.079   |
| November  | 6 | 0.25 | 1.346 | 22 | 25.99 | 4.169   |
| December  | 6 | 0.25 | 1.346 | 19 | 24.98 | 6.248   |

Now we can move ahead with the calculations of the heat pump unit.

#### 4.4.2 Heat Pump Analysis

For calculating the power requirement to the compressor in the heat pump we developed a DWSIM model consisting of the main four subcomponents namely evaporator compressor, condenser and expansion valve. The DWSIM model is shown below.

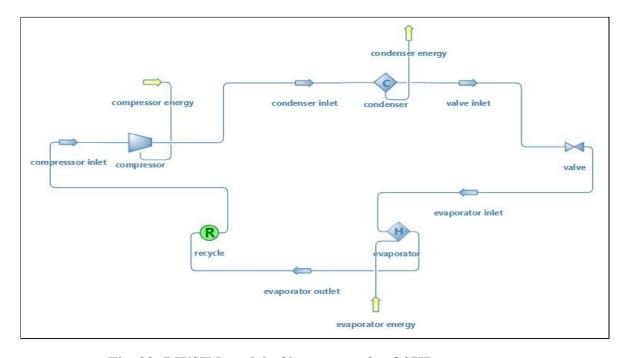

Fig. 23: DWSIM model of heat pump for GSHP system

Taking a closer look at the simulation we can see that energy is fed into the evaporator and compressor and is released from the condenser. The energy input to the evaporator comes from the heat exchanger unit, i.e., the heat load of each month that we have calculated in section 4.4.1. We

assume there is no heat loss and heat is transferred directly from the circulating fluid of the heat exchanger (water) to the refrigerant in the heat pump.

In this DWSIM model we have carefully chosen propane as the refrigerant which has zero ozone depletion potential and negligible global warming potential. We have assumed 100% efficiency of the evaporator and taken pressure drop as 7 Pa (after much research on maximum allowable pressure drop from literary sources). For the compressor we assumed adiabatic process and 100% adiabatic efficiency.

The energy input to the evaporator was taken as the heat duty for the heat exchanger unit as calculated in section 4.4.1. Coefficient of performance is calculated using equation (1) as Qcompressor/Qcondensor where Qcomp is the power that needs to be supplied to the compressor and Qcondensor is the output power of the heat pump.

Master property table for the month of January is shown below.

**Tabel 20: DWSIM Model Master Property Table for January** 

| Master Property Table |                   |                  |                   |    |
|-----------------------|-------------------|------------------|-------------------|----|
| Object                | evaporator energy | condenser energy | compressor energy |    |
| Energy Flow           | 8.327             | 11.7632          | 3.43619           | kW |

The results obtained for each month are given in the table below.

**Table 21: DWSIM Heat Pump Model Results** 

| Month     | Qevaporator (KW) | Qcompressor (KW) | Qcondensor (KW) | COP  |
|-----------|------------------|------------------|-----------------|------|
| January   | 8.327            | 3.43619          | 11.7632         | 3.42 |
| February  | 4.169            | 3.37861          | 7.54761         | 2.23 |
| March     | -8.327           | 3.28062          | -5.04638        | 1.54 |
| April     | -9.371           | 3.27281          | -6.09819        | 1.86 |
| May       | -13.53           | 3.24169          | -10.2883        | 3.17 |
| June      | -15.619          | 3.22605          | -12.3929        | 3.84 |
| July      | -10.416          | 3.26499          | -7.15101        | 2.19 |
| August    | -7.292           | 3.28837          | -4.00363        | 1.22 |
| September | -6.248           | 3.29618          | -2.95182        | 0.9  |
| October   | 2.079            | 3.36523          | 5.44423         | 1.62 |
| November  | 4.169            | 3.37861          | 7.54761         | 2.23 |
| December  | 6.248            | 3.41511          | 9.66311         | 2.83 |

The obtained results are shown graphically for better visualization.

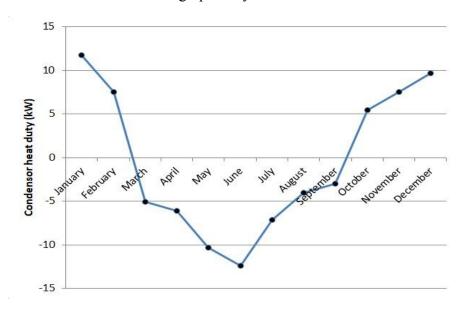

Fig. 24: Condenser heat duty vs. month plot

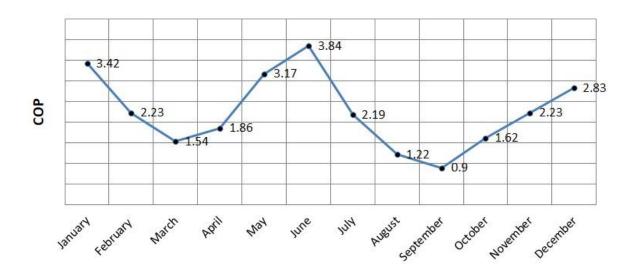

Fig. 25: COP vs. month plot for GSHP

The sign of heat duty of the condenser obtained from the simulation model can easily be analyzed. For winter months like January, February, October, November and December, Qevaporator is positive meaning that heat is supplied to the heat pump, Qcompressor is positive indicating that power needs to be supplied to the heat pump, and Qcondensor is positive which means that energy is being released by the heat pump. This heat can further be used to heat up the circulating fluid in

the secondary loop which can further be transferred to the building. For the remaining months, Qcondensor is negative which means that heat is being extracted from the circulating fluid in the secondary loop by the heat pump which can ultimately be used for cooling. Hence, the results are as required i.e, heating in winter months and cooling in summer months. The COP of each month is also satisfactory with monthly COPs lying in the range of 0.9 -3.8 and average annual COP of 2.25. Hence we can move forward with our calculations.

#### 4.4.3 Radiant Heating/Cooling Unit Analysis

Now that we have completed the calculations of the heat exchanger unit and heat pump unit we are left with the calculation for the secondary loop or building loop consisting of a radiant heating/cooling unit. For this we have to consider heat transfer by convection and radiation both. For simplicity we will be using the concept of combined heat transfer coefficient as recommended by ISO 11855. The combined heat transfer coefficient as given in ASHRAE HVAC Systems and Equipment (2012) for floor/wall/ceiling heating/cooling is 8.29 W/m<sup>2</sup> K. If we multiply equation (2) by the area of the radiant surface on both sides we can calculate the total heat transferred by the radiant system.

Now, in this case we assume that all the energy being supplied by the condenser of the heat pump is absorbed by the circulating fluid in the secondary loop (water) and there are no power losses. For the sake of simplicity, we again assume that the energy being supplied to the circulating fluid in the secondary loop is transferred to the interior of the two story house via the radiant heating/ cooling system. With these assumptions we can say that the total heat transferred by the radiant surface is equal to the power output of the condenser and by dividing by the combined heat transfer coefficient and radiant surface area we can obtain the temperature difference between the walls and room temperature.

For calculating the total radiant surface temperature we assume a piping network in the ceiling and two walls opposite to each other on both floors. The building has a square base of  $300 \text{ft}^2(27.87 \text{ m}^2)$  making the dimensions of the base 17.32 ft  $\times$  17.32 ft  $(5.28 \text{m} \times 5.28 \text{m})$ . The total height of the building is 7.5m making the height of each floor 3.75m. Hence the total radiant surface area of the entire building is given by,

$$A = (27.87 \text{ m}^2 \times 2) + (5.28 \text{ m} \times 3.75 \text{m}) \times 4 = 134.94 \text{ m}^2$$

The results after dividing total heat transferred by radiant surface area and combined heat transfer coefficients (as described above) for each month are shown in the table below.

Table 22: Difference between wall surface temperature and room temperature

| Month     | Qcondensor  (KW) | h <sub>tot</sub> (W/m <sup>2</sup> K) | A(m²)  | Δ <b>T</b> |
|-----------|------------------|---------------------------------------|--------|------------|

| December  | 9.66311          | 8.29                                  | 134.94 | 8.64       |

The temperature differences obtained give a rough idea of how much heating or cooling takes place. The temperature differences are appreciable and we can say that the modeled GSHP system can be used to provide thermal comfort in the two story building to an appreciable extent.

#### 4.4.4 Electricity Cost Analysis

From section 4.3.5, Cost of grid electricity in India = Rs 3/kWh and annual electricity consumption of the GSHP system = 29084.85072 kWh/year

Therefore, Annual electricity cost = Rs (3\*29084.85072) = Rs 87254.55 /year

**Table 23: Heat Pump Electricity consumption** 

| Month     | Qcomp(KW) | time | total power |
|-----------|-----------|------|-------------|
| Jan       | 3.43619   | 744  | 2556.52536  |
| February  | 3.37861   | 672  | 2270.42592  |
| March     | 3.28062   | 744  | 2440.78128  |

| December | 3.41511  | 744 | 2540.84184  |
| Qtotal   | 39.84446 |     | 29084.85072 |

#### 5. Conclusion

We have developed two heating and cooling systems: EAHE and GSHP. Both these Earth integrated systems are viable techniques for preheating the air/water in winter and cooling it in summer. We must calculate the building's heating/cooling load requirement, geometrical constraints, and perform cost analysis in order to design these systems. In the EAHE, air is the heating/cooling medium and in the GSHP, heating/cooling medium. Both the systems are quite energy efficient compared to conventional heating-cooling systems, as indicated by their high COP values. They are able to bring significant temperature differences and we can therefore say that our modeled systems provide thermal comfort in the building. Simulation results show that GSHP can provide 11.08 °C indoor temperature reduction, for the summer peak month (June) in New Delhi. For the same month, from our calculations, the EAHE has the potential for reducing the indoor temperature by 15.51°C. The EAHE also has a higher average COP of 8.153 as compared to 2.25 for the GSHP. Thus, it can be concluded that the EAHE is more efficient than the GSHP system.

#### 6. Future Scope

This study is entirely based on a theoretical analysis of the two heat exchanger systems. It could be taken a step further by relaxing the assumption of constant ground temperature for a given month and taking into account its variability as a result of heat exchange with the working fluid and other natural phenomena at work. Currently, the benefits and performance of solar panels have been analyzed, however, we would like to explore their proper integration with our systems to determine their viability and how much of the electrical energy demanded by the system equipment can be fulfilled. Also, in this study, the determination of heating and cooling loads and heat exchanger performance evaluation have been treated as separate problems. So, we would like to combine the two into a comprehensive whole with the help of a suitable simulation software to get a theoretical understanding of the thermal conditions which would prevail indoors when the heat exchangers are in action. Lastly, a good way to advance the study would be to implement the systems in a real setting to gain better insights, see how our assumptions hold up and how fluctuations in prevalent conditions influence the operation of our systems.

We can also implement the integration of solar panels in the designing of a system of houses called R-2000 houses. Houses which are made on R-2000 technology include features like upgraded insulation, roofing and vapor barrier system that make it 30% more efficient in comparison to a normal house. Non-crystalline panels, which is a Thin-Film solar panel, can be the future of the solar industry because they are not completely made with silicon so they are economical or easy to manufacture

#### 8. Annexure

#### 8.1. Heat Transfer Governing Equation Derivation

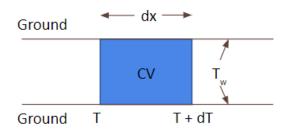

Fig. 26: Horizontal Heat exchanger Pipe-cross section

Energy balance on control volume (CV) gives:

$$\dot{m}C_{p}\frac{T+dT-T}{dx} = 2\pi rh \, dx(T_{w} - T)$$

$$\frac{dT}{T_{w}-T} = \frac{2\pi rh \, dx}{\dot{m}C_{p}}$$

On integrating, we get:

$$-\ln(T_{_{W}}-T)=\frac{2\pi rh\,dx}{\mathrm{m}C_{_{P}}}+C$$

Boundary Condition:  $T = T_{in}$  at x = 0, hence  $C = -\ln(T_w - T_{in})$ 

On substituting, we get:

$$ln\left(\frac{T_w - T}{T_w - T_{in}}\right) = -\frac{2\pi rh \, dx}{\dot{m}C_p}$$

$$\frac{T-T_{w}}{T_{in}-T_{w}} = exp\left(-\frac{2\pi rh\,dx}{\dot{m}C_{p}}\right)$$

On rearranging, we get the final equation:

$$T_{out} = T_w + (T_{in} - T_w)e^{-\frac{2\pi r h x}{inC_p}}$$
